Vapor Phase Elemental Sulfur Amendment for Sequestering Mercury in Contaminated Soil

Scientists at the Savannah River National Laboratory (SRNL) have identified a method of targeting mercury in contaminated soil zone by use of sulfur vapor heated gas.

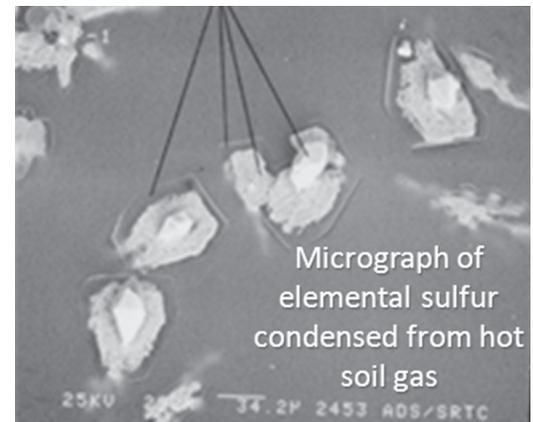

Background

Mercury contamination in soil is a common problem in the environment. The most common treatment is excavation – a method that works well for small sites where the mercury contamination is shallow. Other methods of treating mercury contaminated sites include high temperature soil vapor extraction to remove mercury and deployment of treatment materials in closely spaced boreholes to isolate mercury as it diffuses through the system. SRNL has developed

an improved remediation method to distribute elemental sulfur into contaminated soil to treat elemental mercury. Elemental mercury reacts with the sulfur to form stable compounds with low solubility and low toxicity. Because gases move easily in soil, gaseous delivery of a chemical reagent is a preferred enhancement for many in situ treatment processes.

How it works

This process uses elevated temperature and gas delivery to distribute significant quantities of sulfur throughout a treatment zone (without the need to inject liquids). For sites with small mercury inventories, the proposed method would be less expensive than baseline excavation. When coupled to high temperature soil vapor extraction (sites with large mercury inventories), the process would provide a significant added value for the investment in heating the subsurface and provide a basis for shutting off systems and limiting the time required for expensive heating.

TechBriefs

Savannah River National Laboratory

Technology transfer

The Savannah River National Laboratory (SRNL) is the U.S. Department of Energy's (DOE) applied research and development laboratory at the Savannah River Site (SRS).

With its wide spectrum and expertise in areas such as homeland security, hydrogen technology, materials, sensors, and environmental science, SRNL's cutting edge technology delivers high dividends to its customers.

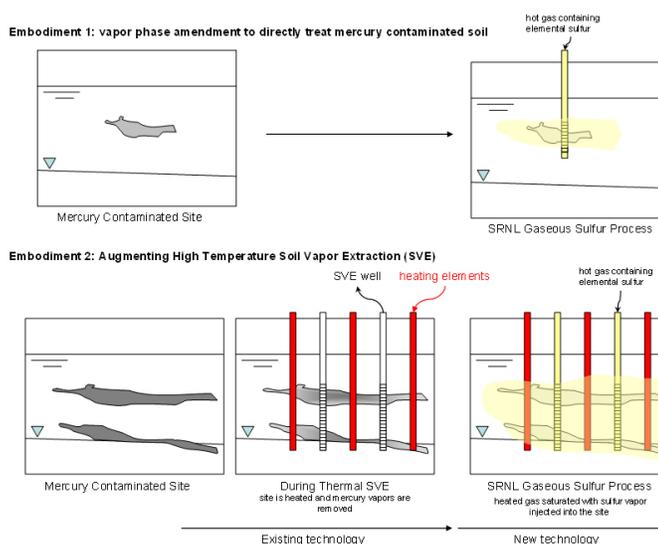

The management and operating contractor for SRS and SRNL is Savannah River Nuclear Solutions, LLC. SRNS is responsible for transferring its technologies to the private sector so that these technologies may have the collateral benefit of enhancing U.S. economic competitiveness.

Direct treatment

For sites that contain small quantities of mercury, process would include injecting the sulfur vapor saturated heated gas into access wells to distribute the gas throughout the site. Solid sulfur will precipitate in the cool soil, react with mercury and leave a residual phase to maintain conditions that limit mercury mobility/availability.

Augment high temperature soil vapor extraction

Recently, soil remediation methods have been developed to remove elemental mercury contamination from soil using high temperature (circa 250C) vapor extraction processes; high temperature heating elements and simultaneous pumping to remove gases containing volatilized mercury from contaminated soil. The augmentation would be applied after the bulk mercury removal is complete and sulfur will chemically combine with and sequester, the remaining mercury in a nontoxic and stable mineral form. This technology would take advantage of high temperature created during the active extraction process to distribute significant quantities of sulfur throughout the treatment zone (without the need to inject liquid/fluids).

Partnering opportunities

SRNS invites interested companies with proven capabilities in this area of expertise to develop commercial applications for this process or product under a cooperative research and development agreement or licensing agreement. Interested companies will be requested to submit a business plan setting forth company qualifications, strategies, activities, and milestones for commercializing this invention. Qualifications should include past experience at bringing similar products to market, reasonable schedule for product launch, sufficient manufacturing capacity, established distribution networks, and evidence of sufficient financial resources for product development and launch.
